In this report, LP Information studies the present scenario (with the base year being 2017) and the growth prospects of global Necrotizing Fasciitis market for 2018-2023.

Necrotizing fasciitis (NF), commonly known as flesh-eating disease, is an infection that results in the death of the body's soft tissue. It is a severe disease of sudden onset that spreads rapidly. Symptoms include red or purple skin in the affected area, severe pain, fever, and vomiting. The most commonly affected areas are the limbs and perineum. Necrotizing fasciitis affects 0.4 to 1.0 person per 100,000 per year. Both sexes are affected equally. It becomes more common among older people and is very rare in children. Surgical debridement (cutting away affected tissue) is the mainstay of treatment for necrotizing fasciitis. Early medical treatment is often presumptive; thus, antibiotics should be started as soon as this condition is suspected. Cultures are taken to determine appropriate antibiotic coverage, and antibiotics may be changed when culture results are obtained. Besides blood pressure control and hydration, support should be initiated for those with unstable vital signs and low urine output. Over the next five years, LPI(LP Information) projects that Necrotizing Fasciitis will register a xx% CAGR in terms of revenue, reach US\$ xx million by 2023, from US\$ xx million in 2017.
