## Abstracts

The global Cadmium Anode market size is predicted to grow from US$ 169 million in 2025 to US$ 225 million in 2031; it is expected to grow at a CAGR of 4.9% from 2025 to 2031.

A cadmium anode is a component used in electroplating processes, primarily for depositing a protective cadmium coating onto metal surfaces. Cadmium plating provides excellent corrosion resistance, particularly in marine and alkaline environments. The anode itself is made of pure cadmium metal, which dissolves during the electroplating process, replenishing the cadmium ions in the plating solution. The deposition of cadmium onto the cathode (the workpiece) creates a sacrificial layer, protecting the base metal from rust and corrosion. However, due to cadmium's toxicity, its use is increasingly restricted, and alternative plating materials are being sought.

The cadmium anode industry is experiencing a significant decline due to environmental regulations and health concerns. Upstream, the production of cadmium anodes is decreasing, with a focus on safer alternatives. Downstream, industries are shifting towards zinc-nickel, tin, or other non-toxic plating solutions. Product specifications are emphasizing the development and adoption of these alternatives, with research focusing on achieving comparable corrosion resistance and performance. The future market size for cadmium anodes is shrinking rapidly, as regulations become stricter and industries prioritize sustainability. The trend is towards the complete phase-out of cadmium plating in most applications.
