Fluorescence endoscopy is a new medical endoscopy technology that has been developed and widely used around the world since 2015. Its operating spectrum is based on the spectral range of 400-900 nanometers. In addition to showing images of

the superficial layers of human tissue, fluorescence imaging of tissues below the surface (such as cystic ducts, lymphatic vessels, and blood vessels) can also be realized at the same time. It plays a key role in accurately locating the lesion area during the operation and reducing the risk of vascular injury easily caused during the operation. There are two forms of fluorescent hard mirror imaging, one is to inject exogenous photosensitizer dye, and the other is to detect the lesions or pre-lesions that are difficult to observe by detecting the fluorescence emitted by the cells themselves. Exogenous photosensitizer dyes can purposefully mark lesion sites such as cancer, and emit fluorescence of specific wavelengths to reveal the details of lesion areas.
