The active filtering device module is a new type of special equipment for harmonic control made of modern power electronics technology and digital signal processing technology based on high-speed DSP devices. It is composed of two main parts: command current operation circuit and compensation current generation circuit. The command current operation circuit monitors the current in the line in real time, converts the analog current signal into a digital signal, and sends it to a high-speed digital signal processor (DSP) to process the signal, separates the harmonic from the fundamental wave, and modulates the signal with pulse width. The form sends driving pulses to the compensation current generating circuit to drive the IGBT or IPM power module, and

generates a compensation current equal in amplitude and opposite in polarity to the harmonic current of the power grid and injected into the power grid to compensate or offset the harmonic current and actively eliminate power harmonics .
