The global Active Noise Cancellation (ANC) Bluetooth Headphone Chip market size is predicted to grow from US$ 6153 million in 2025 to US$ 9960 million in 2032; it is expected to grow at a CAGR of 7.3% from 2026 to 2032.

In 2024, the global production of Active Noise Cancellation (ANC) Bluetooth Headphone Chip will reach 991 million units, with an average selling price of US$5.93 per unit. They are also entering the market with professional audio manufacturers like Harman, Sony, Skullcandy, Edifier, and 1MORE. They are also being used in smart audio products from internet companies like Google, Alibaba, and Baidu. Active noise cancellation (ANC) monitors background noise, uses chips and algorithmic models to calculate noise waves, and generates inverse sound waves. This noise cancellation is achieved through the principle of superposition and cancellation. Currently, digital active noise cancellation is widely adopted in the industry. Whether feedforward, feedback, or a hybrid combination of the two, all rely on noise acquisition by a microphone, processing by a DSP/MCU, and then outputting inverse sound waves for noise reduction. Active noise cancellation can be categorized into three types: feedforward, feedback, and a hybrid combination of the two. Feedforward ANC headphones are typically located externally, collecting noise and feeding it to a DSP for processing, which then outputs inverse sound waves for noise reduction. Feedback ANC headphones have microphones located internally. The noise collected and fed to the DSP is essentially the same as what the ear hears, allowing for direct inverse processing. Hybrid ANC, combining these two approaches, can achieve faster and more effective noise reduction. At present, although the cost of hybrid active noise reduction is relatively higher, as the cost of chips and microphones decreases, this method that can bring a better listening experience will definitely become the first choice of manufacturers.
