Blood tests are commonly used to measure levels of cortisol, adrenocorticotropic hormone (ACTH), and electrolytes such as sodium and potassium. In Addison's disease, cortisol levels are usually low, while ACTH may be elevated due to the lack of negative feedback on the pituitary gland. Electrolyte imbalances, such as low sodium and high potassium, can also indicate adrenal insufficiency. This test involves administering synthetic ACTH (cosyntropin) through an injection and measuring cortisol levels before and after to assess the adrenal gland's response. In Addison's disease, cortisol levels do not increase significantly after ACTH stimulation.

This report presents a comprehensive overview, market shares, and growth opportunities of Addison Disease Testing and Treatment market by product type, application, key players and key regions and countries.
