The global Adult Artificial Heart market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of %from 2026 to 2032.

An adult artificial heart is a medical device that is designed to replace a damaged or diseased heart in an adult patient. It is used as a last resort treatment option for individuals who have end-stage heart failure and are not eligible for a heart transplant. The artificial heart is typically made up of two ventricles, which are responsible for pumping blood throughout the body. These ventricles are connected to an external power source and control unit, which help regulate the pumping action of the artificial heart. The main goal of an adult artificial heart is to provide a patient with a functional circulatory system while they await a heart transplant or as a long-term solution if a transplant is not possible. It can significantly improve the quality of life for patients with severe heart failure, allowing them to engage in normal daily activities. However, there are several challenges associated with adult artificial hearts. These include the risk of infection, blood clotting, device malfunction, and the need for lifelong anticoagulant medication to prevent clotting. Additionally, the external power source and control unit can limit mobility and require the patient to be connected to a power source at all times. Research and development in the field of adult artificial hearts are ongoing, with the aim of improving the design, reducing complications, and increasing the lifespan of these devices.

The future trends of adult artificial hearts are likely to focus on improving the durability, functionality, and compatibility of these devices. Advancements in materials science and engineering will lead to the development of more durable and long-lasting artificial hearts, reducing the need for frequent replacements and improving patient outcomes. Additionally, advancements in sensor technology and data analytics will enable artificial hearts to better mimic the natural function of the human heart, leading to improved overall performance and reduced risk of complications. Furthermore, research into

biocompatible materials and tissue engineering techniques will allow for the development of artificial hearts that are better integrated into the body, reducing the risk of rejection and improving long-term outcomes for patients.
