The global Air Flotation Machine market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of %from 2026 to 2032.

The air flotation machine is a dissolved air system that produces a large number of fine bubbles in the water, so that the air attaches to the suspended particles in the form of highly dispersed tiny bubbles, resulting in a state of density lower than that of water. -Water treatment equipment for liquid separation. The air flotation machine is divided into super-efficient shallow air flotation machine, vortex concave air flotation machine, and advection air flotation machine. It is used in water supply, industrial wastewater and urban sewage treatment. The advantage of the air flotation machine is that its solid-liquid separation equipment has the characteristics of less investment, a small footprint, a high degree of automation, and convenient operation and management.

The air flotation machine is a machine that uses small or tiny air bubbles to make impurities in the medium float out of the water. The air flotation device can be used for some fine particles in the water body whose specific gravity is close to that of water, which is difficult to sink or float due to their own weight. In terms of water supply and drainage, the water quality of pretreatment, except for some raw water with more sand and sewage with heavy mechanical impurities, is mostly light suspended particles. For example: algae in lakes, reservoirs and some rivers; plant residues and fine colloidal impurities; dye particles in the printing and dyeing industry; short fibers in the paper and chemical fiber industries; petroleum and organic solvent droplets in oil refining and chemical industries; Heavy metal ions in pickling wastewater; electrophoretic paint wastewater, etc.; are light particles whose specific gravity is very close to that of water. For these raw water, if the traditional sedimentation method is used, the effect will be very poor, especially in low temperature conditions in winter, due to the deterioration of coagulation and hydraulic conditions, the treatment effect is more difficult to guarantee. It can be imagined that if the flocs that are difficult to settle, if you insist on making them

sink, you will get twice the result with half the effort. It is better to take advantage of the situation and artificially introduce air bubbles into the water body to make them adhere to the flocs, thereby greatly reducing the overall density of the flocs. , and use the rising speed of the bubbles to force it to float up, so as to achieve rapid solid-liquid separation. In this sense, the emergence of air flotation technology is a revolution to the gravity sedimentation method, which opens up a new field of solid-liquid separation technology.
