Engines need fuel to provide the energy needed to produce power. Most planes in the general aviation fleet employ a carburetor to provide a combustible mixture of fuel and air. It is the job of the carburetor to measure the amount of incoming intake air and meter out the proper fuel/air ratio to the cylinder intakes.

The majority of carburetors used in general aviation are the float-type. This means that the carburetor has a bowl which is filled with fuel to a level regulated by a float attached to a needle valve. Fuel enters the bowl through a strainer which filters the fuel. As the fuel level increases, the float rises and the needle valve, which is attached to the float by a lever, closes and shuts off the fuel flow until the float level drops again. Aircraft carburetors are separated into two categories: float-type carburetors and pressure-type carburetors. Float-type carburetors, complete with idling, accelerating, mixture control, idle cutoff, and power enrichment systems, are the most common of the two carburetor types.
