An angular displacement sensor is a sensor used to measure the rotation angle and position of an object. It usually consists of a rotating part and a fixed part, one of which is connected to the rotating object and the other is fixed to the relatively stationary part. As the rotating part moves, the sensor will output a signal related to its motion. The angular displacement sensor adopts a non-contact patented design. Compared with other traditional angular displacement measuring instruments such as synchronous

analyzers and potentiometers, it effectively improves the long-term reliability and has a wide application prospect.
