Antibacterial nanorobots are tiny machines made of gold nanowires (bling-bling) and coated with platelets and red blood cells that can actually clear bacterial infections directly from a patient's blood.

They do this by basically mimicking a bacterium (and its toxin's) target, then ensnaring them in their nanowire mesh when the bacteria gets near.

They can even be directed through a patient's body with targeted ultrasounds to speed up the clearance process and to treat localized infections.

Best of all, because they take advantage of the bacteria's natural responses to clear them from the system, nanorobots can potentially be used in place of broad-spectrum antibiotics which could have an immense impact in our fight against the rise of antibiotic-resistant diseases.
