A deep cycle battery loses a substantial amount of water when gassing takes place during the electrolysis process. As a result, the ratio of water to sulphuric acid drops, causing the battery electrolyte to lose strength. This affects the battery capacity and its overall performance. Sometimes if the electrolyte level is not checked for a long time, it can run very low leaving the plates uncovered. This can cause irreversible damage to a deep cycle power bank. To keep the deep cycle battery in good condition and performing optimally, users need to maintain a proper electrolyte level. Users can do this by regularly checking electrolyte level in battery and refilling with battery water when necessary. The handiest tool for refilling batteries without spilling is a battery filler.
