The global Biodegradability Testing market size is predicted to grow from US$ million in 2025 to US$ million in 2031; it is expected to grow at a CAGR of %from 2025 to 2031.

Biodegradability testing is a process used to determine the rate and extent to which a substance can be broken down by natural biological processes, such as the action of microorganisms. It is an important test conducted on various materials, including chemicals, plastics, and other products, to assess their environmental impact and potential for pollution.

During biodegradability testing, the substance is exposed to specific environmental conditions, such as temperature, humidity, and the presence of microorganisms. The degradation of the substance is monitored over a period of time, and various parameters, such as carbon dioxide production, oxygen consumption, or changes in physical properties, are measured to determine the extent of biodegradation.

The results of biodegradability testing provide valuable information about the environmental fate of a substance. If a substance is found to be readily biodegradable, it indicates that it can be broken down by natural processes and is less likely to persist in the environment. On the other hand, if a substance is found to be non-biodegradable or slow to biodegrade, it suggests that it may accumulate in the environment and have long-term effects.

Biodegradability testing is often required by regulatory agencies to assess the environmental impact of new products or chemicals before they can be approved for commercial use. It helps in the development of more sustainable and environmentally friendly materials and products by identifying substances that are more easily broken
