The birefringence dual-frequency laser interferometer is a high-precision measuring instrument based on the principle of birefringence and dual-frequency laser technology. It measures the phase difference or frequency change of the laser beam caused by the movement of the object to be measured during the measurement process, and then calculates the displacement, length or other geometric quantities of the object to be measured. Birefringence refers to the fact that when light passes through certain media, the optical properties of the medium (such as refractive index) change with the propagation direction or vibration direction of the light wave, causing the light to be decomposed into two or more beams with different vibration directions. In the birefringence dual-frequency laser interferometer, the birefringence element is used to generate two laser beams with different frequencies. Dual-frequency laser technology refers to the laser outputting two laser beams with slightly different frequencies at the same time. The two laser beams produce a phase difference or frequency change due to the movement of the object to be measured during the measurement process, and this change is proportional to the displacement or length of the object to be measured. By measuring this change, the geometric quantity of the object to be measured can be accurately calculated.

The global Birefringence Dual Frequency Laser Interferometer market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of %from 2024 to 2030.
