Bismuth tungstate is a kind of tungstate, of which the appearance is white powder and chemical formula is Bi_2WO_6 . The compound of orthorhombic structure is a new narrow band gap photocatalytic material with visible light response and visible light catalytic activity.

As a new photocatalyst, Bismuth tungstate has the following characteristics: (1) good response to UV and visible light; (2) thermal stability; (3) stable photocatalysis; (4) relatively low cost; (5) environmental friendly.

Due to its special layered structure, it has superior application in surface catalysis than other photocatalyst. The synthetic reaction conditions can be changed to obtain complex multi-level structures by studying and analyzing the synthesis and characterization of Bi_2WO_6 crystals. And this change can improve the photocatalytic activity and will have guiding function to the growth mechanism of this series of oxide nanocrystals.

Bi_2WO_6 is a typical semiconductor material. After irradiation, the electrons are excited by the transition and leave the corresponding holes to form electron hole pairs. These electron holes with strong redox potential are very easy to react with organic compounds and polymers. The narrow energy gap of electron holes endowed them with good response to the visible light, while increasing the recombination probability of these holes.
