Boat radar archaeology, also known as marine radar archaeology or boat-based remote sensing, is a method used to survey and map underwater archaeological sites using boat-mounted radar systems. It involves the use of radar technology to detect and map submerged cultural features, such as shipwrecks, submerged landscapes, and other archaeological remains.

Boat radar archaeology works by emitting radar signals from a boat-mounted antenna, which then bounce off the seafloor and any submerged objects or structures. The radar signals that are reflected back to the antenna are then processed and analyzed to create high-resolution images and maps of the underwater archaeological features.

This method is particularly useful for surveying large areas of the seafloor quickly and efficiently, as it can cover a wide swath of the seabed in a short amount of time. Boat radar archaeology can also penetrate through water and sediment layers, allowing for the detection of buried or partially buried archaeological remains.

The data collected through boat radar archaeology can provide valuable information about the location, size, shape, and condition of underwater archaeological sites. It can help archaeologists and researchers to better understand past human activities, trade routes, maritime landscapes, and the overall history of coastal and underwater environments.
