Bone tumors develop, when cells within a bone divide uncontrollably, forming a lump or mass of abnormal tissue. Most bone tumors are benign (not cancerous). Benign tumors are usually not life-threatening and in most cases, these tumors do not spread to other parts of the body. Depending upon the type of tumor, treatment options are wide-ranging, from clinical observation to surgery to remove the tumor.

Bone health significantly deteriorates with age, and this might lead to a large number of accidents and resultant fractures.

Several ablation techniques are available to treat bone tumors. They offer multiple advantages such as these techniques are minimally invasive, allow targeted tumor destruction, and have low rate of complications.
