The global Camera Graduated Neutral Density Filter market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of % from 2026 to 2032.

Camera graduated neutral density filter is a physical filter commonly used in photography. The main function of this filter is to make up for the lack of native tolerance of the camera's sensor in high light ratio photography, so that the dark and high light areas of the image can be reasonably exposed. Graduated neutral density filters have a distinctive feature in that their filtering effect is gradual. The amount of light transmitted changes gradually from one end of the filter to the other. This gradient design allows the filter to effectively handle scenes with large differences in brightness, such as the sky versus the ground. By placing the darker part of the filter on the brighter part of the frame (e.g., the sky) and the more transparent part on the darker part of the frame (e.g., the ground), the photographer can control the exposure of the different parts of the frame, resulting in a more balanced and natural-looking image.
