Cancer genome sequencing refers to a method used to identify the complete DNA or RNA sequence of cancer cells based on the sequencing of a single, homogeneous or heterogeneous group of tumor cells.

It is a laboratory technique that characterizes DNA or RNA sequences of primary tumor tissue, the tumor micro environment (such as stromal / fibroblast cells), adjacent or distal normal tissue, or metastatic tumor sites. This technique generates information related to identification of nucleotide bases (DNA or RNA), mutation status, copy number and sequence variants, as well as structural variations including fusion genes and chromosomal translocations.
