Abstracts

The report requires updating with new data and is sent in 48 hours after order is placed.

Instead of creating a traditional image of a fingerprint, capacitive fingerprint scanners use arrays of tiny capacitor circuits to collect data. As capacitors store electrical charge, connecting them up to conductive plates on the surface of the scanner allows them to be used to track the details of a fingerprint. The stored charge will be changed slightly when a finger's ridge is placed over the conductive plates. Conversely, an air gap will leave the charge at the capacitor relatively unchanged. An op-amp integrator circuit is used to track these changes, which can then be recorded by an analog-to-digital converter.
