According to our LPI (LP Information) latest study, the global Capillary Rheometer market size was valued at US\$ 33 million in 2023. With growing demand in downstream market, the Capillary Rheometer is forecast to a readjusted size of US\$ 42 million by 2030 with a CAGR of 3.4% during review period.

The research report highlights the growth potential of the global Capillary Rheometer market. Capillary Rheometer are expected to show stable growth in the future market. However, product differentiation, reducing costs, and supply chain optimization remain crucial for the widespread adoption of Capillary Rheometer. Market players need to invest in research and development, forge strategic partnerships, and align their offerings with evolving consumer preferences to capitalize on the immense opportunities presented by the Capillary Rheometer market.

Capillary rheometry has its origins in polymer melt processing, but is also directly relevant to many other material processes such as high speed coating and printing applications. Based on controlled extrusion of a test material, capillary rheometry enables material flow and deformation properties to be characterized under conditions of high force (or pressure), high shear rate and at elevated temperature.

A high-shear, controlled-stress capillary rheometer consists of a heated barrel and a piston that drives molten material through a calibrated die, applying pressure either at a constant speed or a constant shear rate. Die geometry can be changed to measure rheological properties under different conditions. In addition to the most widely used single-bore configuration, there are also twin bore (dual-barrel) instruments that can perform two simultaneous tests under different conditions. There are also on-line capillary rheometers, which are mounted on an extruder. On-line rheometers process a

side stream of melt diverted from the extruder.

However, with on-line capillary rheometers, oxygen is excluded from the testing process, so hygroscopic materials present no problem. Thermosets also can be processed in on-line capillary instruments but not in benchtop capillary models because the resins cure quickly and cannot be cleaned out.

The basics of the capillary rheometry technique are as follows:

The sample under test is loaded into a bore in the temperature-controlled barrel of the capillary rheometer;

A capillary die of known dimensions (diameter and length) is mounted at the bottom of the barrel bore;

A piston is used to extrude the sample through the capillary die, and the resultant pressure is measured at the die entrance;

Shear viscosity is calculated from knowledge of the capillary die dimensions, piston speed and pressure;

The shear rate of the test can be varied to produce a flow curve (viscosity versus shear rate);

Using a twin bore barrel and a 'zero length' die allows simultaneous determination of shear and extensional viscosity.

Capillary rheometry also enables other rheological and process characteristics to be evaluated, including die swell, melt fracture, wall slip, flow/no-flow stress, melt strength, haul off and pVT relationships.

Industry concentration is relatively high. The global market with the top three companies including Malvern, Goettfert and Dynisco. These companies production account for 12%, 9%, 8%, respectively.

In consumption market, the growth rate of global consumption is smooth relatively. North America and Europe are still the mainly consumption regions due to the advanced production technology and rapid development of economy. The consumption of North America are accounting for 22% while the Europe are accounting for 20%.

Capillary Rheometer can be classified as two types, such as Single-barrel and Multi-barrel. It can be widely used in many industries. Such as thermoplastic resin, thermosetting resin, copier toner, rubber material, ceramic material, food, cosmetics, medicine, coating, ink, fiber and so on.
