In the manufacture of the amazing computer 'chips' which have become an integral part of our lives, the first step is to grow large, pure, single crystals of silicon. These single crystals are cut into discs and then polished to a virtually flawless surface. The circuitry laid down on the silicon surface is so miniaturized that even minute scratches are chasms by comparison. The first steps in the polishing process use somewhat standard abrasive polishing methods to smooth the surface and chemical etchants to remove impurities. However, to achieve the final result an abrasive of very small size is needed. Colloidal silica provides such an abrasive.

In semiconductor and light-emitting-diode (LED) production, colloidal silica is a critical component for producing absolutely flat and uniform wafer surfaces. In both industries, colloidal silica performs equally well as a rough surface remover and final polishing additive, and eliminates the need for other surface preparation steps. In chemical-mechanical planarization, colloidal silica is used to flatten out the irregularities in the films applied to the semiconductor substrates during integrated circuit fabrication.

With colloidal silica, different substrates (e.g., silicon, aluminum and sapphire) can be polished to a surface roughness of nanometer, or if needed Angstrom level. In all cases, wafers can be polished to low-defect and ultra-flat surfaces. Colloidal silica is also a key component in the optical lens industry. Following the rough shaping of an optical substrate using a diamond stylus, it is polished to a deformation-free surface using colloidal silica.

The global Colloidal Silica CMP Abrasives market size is projected to grow from US\$

225 million in 2024 to US\$ 291 million in 2030; it is expected to grow at a CAGR of 4.4% from 2024 to 2030.
