A Common Mode Noise Filter is an electronic device or circuit used to suppress common mode noise, which is noise from two conductors or circuits that affect a signal at the same time. This noise usually comes from external electromagnetic interference, power supply noise or other interference sources, which can be added to the signal, causing signal quality to degrade. Common mode noise refers to noise that exists on two conductors (such as signal and ground) at the same time, as opposed to differential mode noise, which is noise that appears on only one conductor. The main goal of a common mode noise filter is to reduce common mode noise to a minimum to ensure clear signal transmission. These filters typically use a variety of electronic components and techniques, such as inductors, capacitors, and operational amplifiers, to capture and eliminate the undesirable effects from common-mode noise. They can be used in a variety of electronic devices and systems, especially in applications that require high signal-to-noise ratios and clean signals, such as audio equipment, communication systems, sensors, and measurement equipment. Common mode noise filters help improve the anti-interference performance of the system and ensure signal accuracy and reliability. Different types of filters can be applied to common-mode noise in different frequency ranges to meet the requirements of specific applications.

The global Common Mode Noise Filter market size is projected to grow from US\$ 745 million in 2024 to US\$ 991 million in 2030; it is expected to grow at a CAGR of 4.9% from 2024 to 2030.
