Confocal imaging incorporates an aperture or pinhole that suppresses out-of-focus light from reaching the image detector, resulting in very sharp images. The pinhole is especially effective at eliminating unwanted scatter from cataracts or corneal opacities since these structures fall far outside the plane of focus. This optical design provides overall image contrast, but can also alter the appearance of some ocular structures because they are slightly out of focus. Retinal structures that scatter light or are slightly elevated will usually appear darker than normal. Although technically an “artifact,” the effect of this tonal shift can enhance visibility of some findings.
