In chemical engineering, biochemical engineering and protein purification, cross-flow filtration is a type of filtration. Cross-flow filtration differs from dead-end filtration in that the feed passes through a membrane or bed, solids are trapped in the filter, and the filtrate is released at the other end. Crossflow filtration gets its name because most of the feed stream tangentially passes through the filter surface rather than entering the filter. The main advantage of this is that the filter cake is substantially washed away during the filtration process, increasing the length of time the filter unit can be operated.
