CVD Lab Grown Rough Diamonds, also known as Chemical Vapor Deposition lab-grown rough diamonds, are synthetic diamonds created using the Chemical Vapor Deposition (CVD) method. In the CVD process, a small natural or synthetic diamond seed crystal is placed in a vacuum chamber. The chamber is then filled with a mixture of gases, typically methane and hydrogen. When the gases are heated to high temperatures and exposed to a microwave plasma or other energy source, carbon atoms are released from the methane gas. These carbon atoms adhere to the seed crystal and gradually form a rough diamond. The process continues until the desired size and quality of the rough diamond is achieved. This method involves the growth of diamond crystals in a controlled laboratory environment. CVD is one of the primary techniques for producing lab-grown diamonds, and it has gained popularity in the gem and jewelry industry. CVD lab-grown diamonds can be produced with a high degree of purity and quality. They have the same carbon crystal structure as natural diamonds, making them virtually indistinguishable from mined diamonds in terms of chemical composition and physical properties. CVD lab-grown rough diamonds are a significant advancement in the diamond industry, offering consumers a responsible and sustainable choice without compromising on the quality and beauty of the gemstone. They are becoming increasingly popular and widely available in the jewelry market.

The global CVD Lab Grown Rough Diamonds market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of %from 2024 to 2030.
