The global Demultiplexer market size is predicted to grow from US\$ million in 2025 to US\$ million in 2031; it is expected to grow at a CAGR of % from 2025 to 2031.

The impact of the latest U.S. tariff measures and the corresponding policy responses from countries worldwide on market competitiveness, regional economic performance, and supply chain configurations will be comprehensively evaluated in this report.

A demultiplexer is a type of electrical routing device and is used in both analog and digital circuitry. For inputs, it has a single signal line and for outputs it has two or more signal lines. Its purpose is to route a single input signal into a particular output channel. The channel is determined by selector inputs, which represent a unique output channel.

Demuxers are often used in conjunction with multiplexers to provide a routing methodology, which saves space in a layout when there are a high amount of data channels. A mux selects from multiple inputs and route that to a single output. That output then goes to the input of the demux and be sent to a specific, selected output. In many cases, this saves a considerable amount of space.

A decoder is a device, which activates an output channel unique to a particular logical value applied to the selection lines. Demuxers can also be used as a decoder device for digital inputs. If the signal of entry is always a logical 1, then the selection lines can be used to route that value through to the appropriate output line. This type of decoder device is called a 1 to n device. Only one output channel at any specific time is routed to the input.
