Dermatophytic onychomycosis is a fungal infection of the nail plate, nail bed, and, in some cases, the skin surrounding the nail plate. It is caused by yeast, dermatophytes, and molds; dermatophytes account for 90% of all cases. The fungus, especially *Trichophyton rubrum*, *Trichophyton mentagrophytes*, and *Epidermophyton floccosum*, infects the skin, hair, or nails. It is often perceived by people to be an active and contagious infection. Onychomycosis may persist or worsen if not treated. The fungi that cause onychomycosis exist in common sites such as floors, soil, socks, and shoes. Therapies for onychomycosis include debridement and drugs. Debridement is time consuming and minimally effective in eradicating the fungal infection. Systemic drug treatment is most effective in treating onychomycosis.

The global Dermatophytic Onychomycosis market size is projected to grow from US\$ million in 2023 to US\$ million in 2030; it is expected to grow at a CAGR of % from 2024 to 2030.
