For DLC classification, it organized DLC types on a pseudo ternary phase diagram and clarified the relationship with deposition methods. DLC films formed with the sputter vapor deposition method and arc PVD method do not contain hydrogen as long as only solid graphite is used as the raw material and no hydrocarbon gas is used. They are characterized by the differences in the amount of sp³-bonded carbon and the structure of the cluster within the range from graphite-like carbon (GLC) that does not contain hydrogen and amorphous carbon (a-C) to tetrahedral amorphous carbon (ta-C). On the other hand, DLC films produced from a hydrocarbon gas using the plasma CVD method always contain hydrogen. These DLC films take the form of hydrogenated amorphous carbon (a-C:H) to hydrogenated tetrahedral amorphous carbon (ta-C:H), which are characterized by the differences in the amounts of hydrogen and sp³-bonded carbon. Thus, DLC is distinguished by the amounts of hydrogen and sp³-bonded carbon, and the cluster structure, which provides information for understanding various behaviors including mechanical (hardness and Young's modulus), optical (refraction, penetration/absorption), electric (conductance), and chemical (changes during an increase in temperature, oxidation, affinity with various materials) behaviors.
