The impact of the latest U.S. tariff measures and the corresponding policy responses from countries worldwide on market competitiveness, regional economic performance, and supply chain configurations will be comprehensively evaluated in this report.

Disproportionated rosin (also known as 'disproportionated rosin acids' or 'DDR') is a type of rosin derivative that is produced by a chemical process called disproportionation.

Rosin is a natural resin derived from pine trees and is commonly used in various industries, including adhesives, inks, coatings, and rubber production. It consists of a mixture of resin acids, mainly abietic acid and related compounds.

During the disproportionation process, the rosin undergoes a chemical reaction that involves heating and treating it with alkalis. This reaction leads to the transformation of certain resin acids into new compounds, resulting in the creation of disproportionated rosin. The main purpose of this process is to modify the properties of the rosin to suit specific applications better.

Disproportionated rosin has several advantageous characteristics compared to regular rosin. It exhibits improved stability, solubility, and resistance to oxidation. These properties make it particularly useful in industries where stability and compatibility with other chemicals are essential.
