Distributed DTU is a data acquisition and terminal control device based on a distributed architecture. It achieves parallel processing and redundant design by distributing data acquisition, processing and control tasks to multiple independent nodes (such as interval units and common units), thereby improving the scalability, efficiency and reliability of the system. Distributed DTU usually consists of several interval units and common units. The interval units are independently installed in each interval switch cabinet to complete the local measurement and control terminal function, while the common units are centrally installed and connected to each other through the bus to cooperate with each other to complete the function of DTU. This structure enables distributed DTU to quickly isolate faults to avoid affecting the operation of the entire distribution network, thereby reducing the losses of power supply and power users.

United States market for Distributed DTU is estimated to increase from US\$ million in 2024 to US\$ million by 2031, at a CAGR of % from 2025 through 2031.
