In this report, we defines distributed file systems and object storage as software and hardware solutions that are based on “shared nothing architecture” and that support object and/or scale-out file technology to address requirements for unstructured data growth. A shared-nothing architecture is a distributed computing architecture in which there is no single point of contention across the system. Distributed file system storage uses a single parallel file system to cluster multiple storage nodes together, presenting a single namespace and a storage pool to provide high-bandwidth data access for multiple hosts in parallel. Data is distributed over multiple nodes in the cluster to deliver data availability and resilience in a self-healing manner, and to provide high throughput and scale capacity linearly. Object storage refers to devices and software that house data in structures called “objects,” and serve clients data via RESTful HTTP APIs, such as Amazon Simple Storage Service (S3) and OpenStack Swift.
