Chemisorption is used to determine the efficiency of a catalyst to promote desired reactions, and to detect degradation of catalytic activity/regeneration over time. In chemisorption, adsorbed gas or vapor molecules split into atoms, free radicals or ions that form chemical bonds with the adsorbed site. This reaction involves electron sharing between the gas and solid surfaces and may be thought of as the formation of surface complexes. Chemisorption can be used to quantitatively determine the number of surface active sites, which can be used to promote specific catalytic reactions. The key factors of chemisorption determination are: surface area of active elements, metal dispersion, surface acidity, exposure rate of active elements, etc.
