Electrochemical machine tool is a special machining method that uses the principle of electrochemical anodic dissolution of metal in electrolyte to process workpieces. During processing, the workpiece is connected to the positive pole of the DC power supply, the tool is connected to the negative pole, and a small gap is maintained between the two poles. Electrolyte flows through the inter-electrode gap, forming a conductive path between the two electrodes and generating a current at the supply voltage, thereby forming an electrochemical anode dissolution. As the tool is continuously fed relative to the workpiece, the metal of the workpiece is continuously electrolyzed, and the electrolysis products are continuously washed away by the electrolyte. Finally, the gaps between the two poles tend to be consistent, and the surface of the workpiece forms a shape that is basically similar to the working surface of the tool. Electrochemical machining has significant advantages for machining difficult-to-machine materials, complex-shaped or thin-walled parts. At present, ECM has been widely used, such as barrel rifling, blades, integral impellers, molds, special-shaped holes and special-shaped parts, chamfering and deburring processing. And in the processing of many parts, the electrolytic machining process has occupied an important and even irreplaceable position.
