In electrodialysis suspended solids which carry positive or negative electrical charges can increase the resistance of the membrane dramatically, are deposited on the membrane surface. However, in electrodialysis the problem has been eliminated to a large extent by reversing in certain time intervals the polarity of the applied electrical potential which results in a removal of charged particles that have been precipitated on the membranes. This technique is referred to as electrodialysis reversal (EDR).

EDR's ability to perform at very high water recovery due to its polarity reversal which allows for treatment, without any chemicals, of feeds with concentrated salt scale factors well beyond saturation. It is widely used in industrial water treatment. For example, demineralization of boiler feed-water; desalination of industrial wastewater for reuse; recover of valuable electrolytes or acids from rinsing baths in metal (surface) treatments, etc.
