The global Electrolyzer Nickel Base Electrode market size is predicted to grow from US\$ 100 million in 2025 to US\$ 165 million in 2032; it is expected to grow at a CAGR of 7.5% from 2026 to 2032.

Electrolyzer nickel-base electrodes are key components in electrochemical devices that use electricity to split water into hydrogen and oxygen. These electrodes, typically made of nickel or nickel alloys (e.g., nickel-iron, nickel-molybdenum), serve as catalysts to facilitate the hydrogen evolution reaction (HER) at the cathode and the oxygen evolution reaction (OER) at the anode. Nickel is chosen due to its relatively good electrocatalytic activity, corrosion resistance in alkaline electrolytes, and cost-effectiveness compared to more noble metals.

The industry trend for electrolyzer nickel-base electrodes is driven by the increasing demand for green hydrogen production. Key trends include improving the electrocatalytic activity and durability of nickel-based materials through alloying, surface modification (e.g., coatings, nano-structuring), and the development of novel electrode architectures. Research is focused on enhancing the performance of both the HER and OER, particularly the OER, which is often the rate-limiting step in water electrolysis. There's a strong push to reduce or eliminate the use of precious metal catalysts (like platinum or iridium) to lower costs. This involves developing advanced nickel-based catalysts with comparable or superior performance. Another trend is the development of more stable and corrosion-resistant electrodes for operation in different types of electrolyzers, such as alkaline, proton exchange membrane (PEM), and solid oxide electrolyzers. There's also a growing interest in using earth-abundant materials and sustainable manufacturing processes for electrode production. The overall goal is to achieve high efficiency, long-term stability, and cost-effectiveness for large-scale

hydrogen production.
