The global ETC System market size is predicted to grow from US\$ 9743 million in 2025 to US\$ 14410 million in 2031; it is expected to grow at a CAGR of 6.7% from 2025 to 2031.

The impact of the latest U.S. tariff measures and the corresponding policy responses from countries worldwide on market competitiveness, regional economic performance, and supply chain configurations will be comprehensively evaluated in this report.

Apologies for the confusion. The driving factors of the ETC system are primarily based on the principles of thermodynamics and the inherent properties of the electron carriers involved. These driving factors include:

1. **Redox Potential:** The ETC relies on the transfer of electrons from electron donors such as NADH and FADH₂ to electron acceptors such as molecular oxygen. This movement of electrons is driven by the difference in redox potential between these compounds. As electrons flow from donors with higher redox potential to acceptors with lower redox potential, energy is released and utilized for ATP synthesis.
2. **Coupling of Electron Transport and Proton Pumping:** As electrons are transported through the ETC, the energy released in each step is utilized to actively pump protons across a membrane (e.g., mitochondrial inner membrane). This process creates a proton gradient, with a higher concentration of protons on one side of the membrane compared to the other. The coupling of electron transport and proton pumping serves as a driving factor for ATP synthesis by providing the necessary electrochemical gradient.
3. **Chemiosmosis:** The proton gradient generated by the ETC drives the process of chemiosmosis. Protons are facilitated to flow back across the membrane via ATP synthase, an enzyme complex. This flow of protons, known as proton motive force,

combines the chemical potential (concentration gradient of protons) and the electrical potential (difference in charge across the membrane) to drive the formation of ATP from ADP and inorganic phosphate (Pi).

4. Oxygen as the Final Electron Acceptor: The availability of oxygen is critical for driving the ETC. Molecular oxygen serves as the final electron acceptor, receiving electrons at the end of the chain. Without the presence of oxygen, the ETC cannot remove electrons from its carriers, leading to a buildup of intermediates and the halting of the process.

5. NADH and FADH₂ Levels: The levels of NADH and FADH₂, which act as electron donors, influence the rate of electron transport. The availability of NADH and FADH₂ depends on the metabolic state of the cell and the substrates available for oxidative metabolism. Higher levels of NADH and FADH₂ increase the electron flow in the ETC, driving ATP synthesis.
