A five-axis probe station is a device for precision measurement and machining that has five axes of independent movement. It usually consists of a base and a mobile platform that can move freely in multiple axes. The main function of the five-axis probe station is to locate and measure the coordinates and surface features of objects in three-dimensional space. It is commonly used in manufacturing, engineering, and scientific research, for example in applications such as part machining, precision measurement,

optical assembly, and 3D scanning. Through the combination of five independent movement axes, the five-axis probe station can achieve more flexible and precise motion control. The machine is capable of linear motion along the X, Y, and Z axes, and can rotate about two rotational axes. This multi-axis motion structure enables the five-axis probe station to measure and process in multiple angles and directions, thereby achieving more complex operations and higher precision. Five-axis probe stations are usually equipped with precision measurement sensors, such as probes, laser sensors or optical sensors, to measure the size, shape and surface characteristics of objects. It can also be integrated with computer systems for automated control and data analysis.
