The global Flat-top Comb Filter market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of % from 2026 to 2032.

The flat-top comb filter is a digital filter used for signal processing. It is designed to remove unwanted frequency components from the signal while retaining the desired frequency components. The comb filter works by adding a delayed version of the signal to the original signal. The delay time is usually equal to the period of the frequency to be filtered out. When two signals are added, the frequency components that are in phase with each other are added, while the components that are out of phase cancel each other. The flat-top comb filter is designed to minimize the ripple in the frequency response of the filter so that the output signal has a flat response in the passband. This is important in applications where the frequency response of the filter needs to be as flat as possible, such as in audio and video signal processing.
