The global Food Irradiation Testing market size is predicted to grow from US\$ million in 2025 to US\$ million in 2031; it is expected to grow at a CAGR of % from 2025 to 2031.

Food irradiation testing is the process of subjecting food products to ionizing radiation in order to kill bacteria, parasites, and other pathogens that may be present. This testing is done to ensure that the irradiation process is effective in reducing the microbial load of the food and to determine the appropriate dosage of radiation required for different types of food.

During food irradiation testing, samples of the food product are exposed to a controlled amount of radiation, typically gamma rays or electron beams. The samples are then analyzed to determine the effectiveness of the irradiation process in reducing the microbial load. This testing may also involve evaluating the sensory qualities, nutritional content, and shelf life of the irradiated food.

Food irradiation testing is an important step in ensuring the safety and quality of irradiated food products. It helps to determine the appropriate dosage of radiation required to achieve the desired microbial reduction without compromising the nutritional value or sensory qualities of the food. This testing is typically conducted by regulatory authorities, food manufacturers, and research institutions to comply with food safety standards and regulations.
