## Abstracts

The global Fossil Fuel Energy market size is predicted to grow from US\$ 681710 million in 2025 to US\$ 984040 million in 2032; it is expected to grow at a CAGR of 5.5% from 2026 to 2032.

Fossil fuels can be burned to produce energy, power engines, or provide heat for immediate use. Before burning some fossil fuels are refined to produce compounds such as kerosene, gasoline, and propane. A fossil fuel is a hydrocarbon-containing substance that is extracted and burned as fuel. Examples of fossil fuels include coal, oil, and natural gas.

Rapid industrialization in developed & developing countries and surge in manufacturing processes & production units are the key growth factors driving the demand for fossil fuel energy. The ability of fossil fuels to produce massive amounts of electricity in a single go is one of its main advantages. However, governments of various countries are enacting restrictions to reduce the amount of electricity generated by fossil fuels due to growing environmental concerns. Power plants using fossil fuels are a significant source of harmful pollutants carbon emissions, sulfur dioxide, and mercury. Around 25% of the world's greenhouse gas emissions, or 40% of the carbon emissions produced by the energy sector, come from the power generation industry. To prevent negative environmental effects, regulatory agencies are implementing strict limits on thermal power generation. These regulations are anticipated to raise the cost of obtaining less expensive fossil fuel-based power, acting as a limitation on the market for fossil fuel energy.
