Vapor phase reflow soldering is also called vapor phase soldering (VaporPhaseSoldering, VPS), also known as condensation soldering (condensations soldering). Heating fluorocarbons (FC-70 chlorofluorocarbon solvents used in the early stage), the melting point is about 215°C, and boiling produces saturated steam. There

are condensation pipes on the top and left and right of the furnace to limit the steam in the furnace. When encountering low temperature soldering Latent heat of vaporization is released during PCB assembly, which melts the solder paste and solders components and pads. It was first used in the welding of thick film integrated circuits (IC) in the United States. The release of latent heat of gas cypress is not sensitive to the physical structure and geometry of SMA, which can make the components evenly heated to the welding temperature, and the welding temperature can be kept constant without using temperature control means. To meet the needs of welding at different temperatures, the gas phase of VPS is saturated steam with low oxygen content and high heat conversion rate, but the cost of solvent is high, and it is a typical ozone layer depleting substance, so its application is greatly restricted. This environmentally damaging method is basically no longer used.
