Abstracts

The global Hull Cleaning Robot market size is predicted to grow from US$ 28.32 million in 2025 to US$ 64.33 million in 2032; it is expected to grow at a CAGR of 9.7% from 2026 to 2032.

In 2025, the global production of Hull Cleaning Robots was approximately 464 units, with an average global market price of approximately US$62,400 per unit. The total global production capacity of ship hull cleaning robots reached 700 units in 2025. The industry average gross profit margin for this product reached 38%.

Hull cleaning robot is a new type of robot, which is fully or semi-automatically controlled. The Hull cleaning robot can inspect the hull underwater and perform cleaning work on the hull, which is ideal for cleaning large ships. It can make the cleaning process safe and economical.

According to statistics, the annual cleaning cost of the global shipbuilding industry is close to 10 million US dollars. Therefore, cleaning the biological layer attached to the surface of the ship is very important. It can not only save energy and reduce emissions, extend the docking cycle of the ship, ensure the efficiency of ship transportation, but also reduce fuel consumption and transportation costs from an economic perspective. Using manual cleaning of ships not only takes a long time, but also requires high costs. The hull cleaning robot is highly intelligent and requires relatively low costs. Therefore, it has received widespread attention from various countries around the world.

Algae, slime, and barnacles adhering to the ship's hull surface increase drag, leading to higher fuel consumption, carbon emissions, and operating costs. As international shipping carbon intensity management strengthens, shipowners are shifting from temporary maintenance to routine energy efficiency management of hull cleaning. Robots can perform cleaning during non-stop operation or normal port calls, reducing

dry-docking visits and operational interruptions. Their fuel savings and return on investment are relatively easy to quantify, making them more readily adopted by large fleets.

Ship biofouling not only affects energy efficiency but can also cause the cross-regional spread of invasive aquatic species. Traditional underwater scrubbing can directly release marine organisms, heavy metals, and antifouling coating particles into port areas. Therefore, more and more ports are emphasizing fouling capture, filtration, and operational record-keeping. Robots with negative pressure recovery, multi-stage filtration, non-destructive coating cleaning, and pre- and post-cleaning image retention capabilities are more likely to obtain port approval and command higher technology premiums.

Boat cleaning involves hazardous environments such as turbid water, low visibility, strong currents, propellers, and narrow structures. Divers also face risks of entanglement, mechanical injury, and contaminant exposure. Robots can perform long-duration, repetitive, and large-area cleaning tasks, and are remotely monitored via sonar, cameras, and sensors. As propulsion, permanent magnet motors, underwater connectors, artificial intelligence recognition, and autonomous navigation technologies mature, equipment reliability and cleaning efficiency improve, while procurement and maintenance costs gradually decrease.

Manufacturers are shifting from one-off equipment sales to leasing, pay-per-use, annual subscriptions, and Robots as a Service (Robotics) models, enabling small and medium-sized ship owners to reduce initial investment. Hull cleaning robots can also be extended to warships, fishing vessels, offshore platforms, port ballasts, dams, and offshore wind power infrastructure, simultaneously performing fouling rating, coating inspection, and corrosion checks. In the future, companies that can establish cross-port operating networks and integrate robots, environmental treatment, data platforms, and hull performance management are more likely to create sustainable revenue streams and competitive barriers.
