The global Hybridization Buffer market size is predicted to grow from US\$ million in 2025 to US\$ million in 2032; it is expected to grow at a CAGR of % from 2026 to 2032.

Molecular hybridization is a technique for determining the sequence of single stranded nucleic acid bases. The basic principle is to form detectable double helix fragments between the tested single stranded nucleic acid and a known sequence of single stranded nucleic acid (called a probe) through base pairing. Currently, solid-phase hybridization is widely used. This method involves first binding the single stranded nucleic acid sample to the membrane (if it is double stranded, it must be denatured into a single stranded), and then hybridizing it with the labeled probe in the solution. Hybrid buffer usually refers to a solution commonly used in molecular biology hybridization experiments. It is usually used to maintain a specific pH value and contains some specific salts to maintain the stability and activity of biological molecules (such as DNA, RNA, or proteins) during the experimental process.

United States market for Hybridization Buffer is estimated to increase from US\$ million in 2025 to US\$ million by 2032, at a CAGR of % from 2026 through 2032.
