The global Hyperthermia Therapy for Cancer market size is predicted to grow from US\$ 439 million in 2025 to US\$ 643 million in 2032; it is expected to grow at a CAGR of 5.7% from 2026 to 2032.

Hyperthermia therapy for cancer, also known as thermal therapy or thermotherapy, is a type of treatment in which body tissue is exposed to high temperatures (up to 113°F or 45°C) to damage and kill cancer cells. This approach can enhance the effectiveness of other treatments such as radiation therapy and chemotherapy. Hyperthermia is typically used to treat tumors located in specific parts of the body, such as the chest, liver, or limbs. The heat can be applied using various techniques, including external applicators, internal probes, or perfusion methods where heated substances are circulated through the body. The primary goal is to target cancer cells while minimizing damage to surrounding healthy tissue.

The hyperthermia therapy for cancer market is witnessing growing interest due to its potential to enhance the effectiveness of conventional cancer treatments such as radiation and chemotherapy. As a non-invasive or minimally invasive technique, hyperthermia therapy appeals to both clinicians and patients seeking targeted therapeutic options with fewer systemic side effects. Technological advancements in thermal delivery systems and imaging-guided precision are further improving clinical outcomes and driving innovation. Although still considered an adjunct treatment in many oncology protocols, the increasing number of clinical studies and expanding awareness of its benefits suggest that hyperthermia therapy is poised to become a more integral component of comprehensive cancer care strategies in the coming years.
