The global IGBT Wire Bonding Equipment market size is predicted to grow from US$ 914 million in 2025 to US$ 1483 million in 2032; it is expected to grow at a CAGR of 7.3% from 2026 to 2032.

Wire bonding is a technique that connects tiny electrodes on a chip to external circuits. The function is to connect the chip electrodes with the DBC board using metal wires, forming an internal electrical connection within the module. In IGBT modules, the quality of wire bonding directly affects the electrical performance and reliability of the module. When wire bonding, it is required that the wire diameter of the bonding wire is appropriate and the length is equal; The bonding points are firmly connected, evenly distributed, and meet the flow requirements. In the field of semiconductor packaging, metal leads are the bridge connecting chips and external circuits, directly affecting the performance of chips. Therefore, the quality of wire bonding is crucial. The material, diameter, bonding pressure, bonding time, and bonding temperature of the metal wire can all affect the bonding quality. For example, if the diameter of the metal wire is too large, it will increase parasitic inductance and affect the high-frequency performance of the module; However, a diameter that is too small can lead to insufficient bonding strength and reduce the reliability of the module. Therefore, optimizing these process parameters is the key to improving the quality of wire bonding. At present, the commonly used bonding wires for IGBT include aluminum wire, copper wire, aluminum clad copper wire, etc.IGBT wire bonding equipment is mainly used to connect the small electrodes on IGBT chips with external circuits, and achieve electrical connections inside the module through metal wires (such as aluminum wires, copper wires, etc.). This type of connection not only requires good electrical performance, but also requires sufficient mechanical strength and reliability to ensure the stable operation of IGBT modules in long-term use.
