The global Implantable Infusion Port market size is predicted to grow from US\$ 577 million in 2025 to US\$ 897 million in 2032; it is expected to grow at a CAGR of 6.5% from 2026 to 2032.

Implantable infusion port is a closed vein infusion device that is completely implanted subcutaneously and can be left in the body for a long time. It consists of two parts: an injection base (infusion port base) that can be punctured and a venous catheter connected to it. Through a small surgery, the tip of the catheter is placed in the central vein (such as the superior vena cava), and the injection base is completely buried in subcutaneous tissue in areas such as the clavicle or chest wall. When in use, medical staff need to use specialized non-invasive needles to puncture the injection site through the skin for drug infusion, intravenous chemotherapy, parenteral nutrition support, or blood collection. Its core advantage lies in effectively avoiding the pain of repeated peripheral venipuncture, reducing the risk of drug extravasation and the incidence of central venous catheter-related infections. At the same time, due to the device being completely buried subcutaneously, patients can shower normally and engage in mild activities during treatment intervals, significantly improving the quality of life and treatment comfort of long-term treatment patients (such as tumor chemotherapy).

The midstream of the implantable infusion port industry chain is mainly composed of manufacturers of infusion ports and supporting specialized needles. With high technological barriers and strong pricing power, this link generally maintains a lucrative profit margin. Although the public information does not directly disclose the gross profit margin of the infusion port itself, as a high-value consumable of the same type, the specialized needle for implantable drug delivery devices has been included in the scope of centralized procurement, with a gross profit margin of about 58%.

The average price of implantable infusion ports in 2025 is 280 US dollars per piece, with a sales volume of 2.1071 million pieces and a total production capacity of 2.96 million pieces.

The implantable infusion port has evolved from a simple "chemotherapy venous access" to a landmark solution that balances treatment benefits and quality of life in the era of chronic disease management for tumors. With targeted and immunotherapy significantly extending the survival of cancer patients, the shortcomings of traditional repeated peripheral puncture and peripheral central venous catheter (PICC) in terms of long-term catheterization comfort, infection risk, and daily life restrictions have become increasingly prominent. The infusion port completely eliminates the "tail" exposed outside the body by completely concealing the catheter opening under the skin, fundamentally reducing the risk of catheter-related bloodstream infections and thrombosis. Although its initial implantation cost is high, for patients who require long-term chemotherapy or parenteral nutrition, its extremely low long-term maintenance cost, lower incidence of complications, and ability to allow patients to bathe normally and engage in high-intensity activities form significant health economic advantages. Therefore, from a global perspective, the infusion port is an important technical support for upgrading the modern tumor treatment concept of "high-quality survival with cancer".

The future trend of implantable infusion ports will evolve around four directions: intelligent monitoring, minimally invasive implantation, material innovation, and industrial upgrading. At the level of technological innovation, devices are developing towards "smart ports" that integrate biosensors and IoT technology, such as real-time warning of infection risks through built-in pH and lactate sensors, or wireless monitoring on mobile phones through NFC near-field communication; Domestic enterprises are also integrating technologies such as optical cell detection into port systems, exploring new paths for real-time dynamic monitoring. At the clinical operational level, implantation technology is upgrading from the traditional "blind puncture" to the dual guidance and precision mode of "ultrasound guidance+electrocardiogram positioning". This not only achieves visualization and synchronization of intraoperative "puncture positioning", greatly reducing the risk of radiation exposure and vascular damage, but also promotes new approaches such as hand arm ports due to their aesthetic appeal and convenience. In addition, with the continuous breakthroughs of domestic brands in 3D printing, anti infective coatings, and biocompatible materials, as well as the reshaping of the market pattern by centralized procurement policies, product accessibility will be greatly improved, and the industry is transforming from relying on imported "high-value

consumables? to independently controllable ?universal intelligent terminals?.
