The global Indirect Extrusion Presses market size is predicted to grow from US\$ 473 million in 2025 to US\$ 644 million in 2031; it is expected to grow at a CAGR of 5.3% from 2025 to 2031.

The container and the billet move together while the die and the ram remain in place. This process is carried out through the use of a stem which must be longer than the container. As a result, the billet is pushed through the die, which remains stationary.

In indirect extrusion, also known as backwards extrusion, the billet and container move together while the die is stationary. The die is held in place by a 'stem' which has to be longer than the container length. The maximum length of the extrusion is ultimately dictated by the column strength of the stem. Because the billet moves with the container the frictional forces are eliminated.
