Abstracts

The global Industrial Rainwater Recovery System market size is predicted to grow from US$ 2935 million in 2025 to US$ 4907 million in 2032; it is expected to grow at a CAGR of 7.4% from 2026 to 2032.

Cooling Tower Water Treatment System refers to an integrated equipment package used to monitor, condition, filter, disinfect and control the water circulating through an evaporative cooling tower, closed-circuit cooler spray loop or evaporative condenser.

The system may include conductivity, pH, ORP, residual-disinfectant and corrosion sensors, chemical dosing pumps, blowdown controls, side-stream filters, makeup-water treatment, non-chemical conditioning devices and remote monitoring.

The 2025 benchmark ASP is US$58,000 per system, global sales volume is approximately 51.724k systems, and the modeled average gross margin is approximately 34%.

The upstream industry chain includes metering pumps, sensors, analyzers, controllers, valves, filters, pumps, tanks, piping, electrical components and treatment media.

The midstream includes water analysis, process design, equipment manufacturing, skid integration, software configuration, factory testing and commissioning.

The downstream mainly covers commercial HVAC, data centers, power generation, chemicals and petrochemicals, manufacturing, food and beverage, pharmaceuticals and other facilities using evaporative cooling.

Cooling tower water treatment is a balance between scale control, corrosion protection, microbiological management, suspended-solids removal and water conservation. Improving only one parameter can create new operating risks elsewhere in the system.

Evaporation removes relatively pure water while dissolved minerals remain in the circulating water. Conductivity-based blowdown is therefore widely used to control the concentration of dissolved solids and maintain the selected cycles of concentration.

Increasing cycles of concentration reduces makeup water and blowdown volume, but raises the risk of mineral precipitation, corrosion and chemical instability. The maximum practical cycle depends on makeup-water chemistry, operating temperature, treatment program and materials of construction.

Chemical feed should respond to actual water demand rather than relying only on fixed timers. Flow-paced dosing and online analytical control can improve treatment consistency when cooling load, evaporation or makeup-water quality changes.

Side-stream filtration does not treat the full circulating flow during each pass. It continuously treats a selected portion of the loop, gradually reducing suspended solids and protecting heat exchangers, tower fill and basins.
