An inhalation exposure system is a laboratory device used in the study of inhalation drug delivery or inhalation toxicity. The respiratory system is the main way for oxygen to enter the human body, and drugs or toxic substances can also enter the human body through the respiratory system. The inhalation exposure system is to allow experimental animals to inhale drugs or toxic substances in a controlled manner under laboratory conditions to conduct research on drug safety and effectiveness or toxicological

effects. The inhalation exposure system usually consists of several parts such as generator, monitoring and control part, exposure chamber, and exhaust gas treatment. The experimental drug is in the form of dust, or in the form of solution after being dissolved in liquid, and generates dust aerosol or liquid aerosol in the generator, or volatilizes into gas and enters the exposure chamber. During the experiment, the control of the drug dose, the control of the airflow balance in the exposure chamber, the control of the experiment time, and the monitoring of the experimental environment parameters (oxygen, carbon dioxide concentration, temperature and humidity, pressure in the exposure chamber, etc.) require an automated system to be done. This automated system is the monitoring and control part of the inhalation exposure system.
